CLEANER is smarter
How Air Intake Filters Save Time, Money and HVAC Equipment
MANY BUILDING SUPERVISORS OR MANAGERS DON’T REALIZE THE IMPORTANCE OF PROPER AIR FLOW.

But the costs of ignoring optimal airflow can be substantial—to staff, to technology and to the HVAC system itself. Fortunately, improper air flow, in addition to related HVAC issues, can be eliminated with the use and care of air intake filter screens. These provide reliable, relatively inexpensive, air flow protection. But before we delve into air intake screens, let’s see why optimized air flow in commercial buildings is so important.
THE HUMAN COSTS OF IMPROPER AIR FLOW

Long indoor workdays can lead to numerous health issues related to poor air ventilation and quality. According to OSHA (U.S. Department of Labor, Occupational Safety and Health Administration), poor indoor air quality can cause fever, coughs, shortness of breath and asthma. It can also lead to more serious health problems such as lung cancer and heart disease. Many of the shorter-term issues can be characterized under the relatively broad subject of Sick Building Syndrome. Sick Building Syndrome, an illness marked by headaches and respiratory problems, is “the main cause of absence from work and low efficiency of staffs and employees” according to the U.S. National Library of Medicine.

Numerous studies have also shown that poor air quality hinders employee performance. Workers in environments with poor air quality or inadequate circulation are often sluggish, complain of being tired, and may make decisions slower and with more errors. On the other hand, good air quality can boost performance. A study completed by Harvard and Syracuse Universities showed cognitive ability doubled in buildings with “green building conditions.” This was defined as buildings with higher rates of ventilation and reduced volatile organic compounds.

Even a relatively small amount of poor air quality can be detrimental. As reported by the U.S. National Library of Medicine (in a report titled, The effects of indoor air quality on performance and productivity) decreased employee productivity due to poor air quality can occur even “at pollutant levels that had no measurable effects on the perception of air quality by the occupants themselves.”

THE HIGH TECH EQUIPMENT COSTS OF IMPROPER AIR FLOW

While the human costs of poor air quality have significant financial implications, the costs to high tech equipment are potentially even higher. Mold, fungus and bacteria are not only harmful to people, but to machines. They can grow unchecked in humid and unventilated areas, infecting equipment and greatly reducing its longevity. Indoor contaminants can also corrode circuitry including circuit boards (especially in older machines), as well as solder joints and conductive passageways. Furthermore, improper airflow can create “hot spots” that are harmful to sensitive equipment, which often work best in cool, dry conditions. Hot spots are especially problematic in Data Centers, although they can occur in any building interior that lacks good airflow.

KEEPING HVAC SYSTEMS RUNNING

HVAC systems are complex, but the concept is fairly simple. Draw in air, condition it, and then redistribute, recycle or exchange it within an environment. This all works quite nicely, assuming the airflow isn’t blocked. That’s when problems can start.

To maintain proper airflow HVAC units need to be kept clean and free from damage. That may seem obvious, but remember that components of the HVAC system are outdoors on the roof, where they are out of sight and “out of mind.” Sitting up there, usually without any sort of protection, leaves them vulnerable to hail, as well as high winds and storms, pests and airborne debris. With all these outside elements creating potential obstacles, it’s quite a marvel that these units work as well as they do!

Cottonwood is a particularly frustrating problem. Generated by the poplar tree and common in many areas of North America, the cottonwood debris season lasts from May thru early August. Dense airborne cottonwood may necessitate frequent, even weekly, HVAC air intake fin and coil cleanings. But every season poses its own threats. For example, during late autumn, trees drop their leaves, much of which blows around and seems to eventually end up inside HVAC equipment.
Here are the main threats that restrict HVAC air flow:

- Airborne debris clogging equipment air intakes
- Fin damage from hail and storms—the outside fins on the machine can become dented and pressed against each other, restricting the flow of air
- Condenser coils damage—these are needed to facilitate the transfer of heat from the refrigerant to the outside air
- Prematurely dirty air filters that force equipment to work harder and run longer, resulting in higher energy costs, equipment breakdown, and reduced equipment longevity
- Torn or damaged filters, often the result of moisture or environmental exposure, which may be unable to capture contaminants at all

But ongoing care, cleaning and upkeep will lower HVAC energy costs, as well as repair costs and more.

THE HIGH COST OF HVAC CLEANING

If only upkeep was simple and inexpensive. Unfortunately, it is often neither. One problem is access: rooftop equipment can be inconvenient to reach.

Even in cases where rooftop access is relatively easy, rooftops often lack a convenient water supply. A typical coil cleaning can use 90 gallons of water just to flush out the chemicals—so the lack of hoses and water makes cleaning a system challenging, and almost impossible when cleaning multiple units (and that’s assuming they aren’t in an area with water shortages). The cost of water can be high—in some areas water costs are higher than that of electricity. Also, some regions must adhere to strict EPA guidelines on chemical runoff. This makes rinsing a bit more complicated than merely aiming a hose. To make things even more challenging, high-pressure cleaning can damage the aluminum fins, especially if using untrained labor.

But don’t even think about cleaning an HVAC unit without water. Some cleaning solutions, such as coil cleaners, are corrosive and damage equipment over time if not thoroughly rinsed. With all these obstacles HVAC coil cleaning, which is usually a two-person job, can take hours per unit.

FRESH AIR SCREENS TO THE RESCUE

Fortunately, many of these issues can be greatly reduced with custom air intake screens (also referred to as cottonwood filter screens or air intake screens). These air intake filters are attached to the outside of an HVAC unit, where they act as the first line of defense in keeping larger particles, bugs, cottonwood and other debris out of the equipment. When properly installed and measured, outside air intake filters can deliver long-lasting and reliable protection.

AND DON’T FORGET ABOUT HAIL NETTING

Hail guards, or hail netting, are also worthwhile investments. According to the National Weather Service, hail causes more than one billion dollars in annual damage in the United States alone. Rooftop units don’t have much protection from hail, which can plummet down to earth at incredible speed and be five inches in diameter or greater.

The average cost per square foot to replace a rooftop coil is well over $200. Cut-to-fit hail guard netting however, reduces your risk of air intake damage by deflecting airborne objects and protects your equipment for 10% of the cost of one repair. Hail netting is a great retrofit option versus costly full metal jackets or metal louvers.
PREVENT PROBLEMS WITH *PreVent*®

While there are many air intake screens, the Permatron PreVent® system provides a simple and superior option. PreVent filter screens are not only made with high-quality UV protected black polypropylene media, but they are the only filter screen featuring powerful MagnaMount® earth magnets. These magnetic mounts allow the screens to be installed in minutes, without any drilling or tooling. The filters can be removed for periodic maintenance just as easily, although they won't need to be removed often—PreVent filter screens can be cleaned in place, by brushing them down. In addition to extending equipment life, some companies have lowered their HVAC maintenance costs up to 2/3 by installing PreVent filters. Taking the time to install a screen such as a PreVent filter on rooftop RTUs, cooling towers, cooling fans, or any other equipment can end up saving a company a lot of time, and even better—a lot of money.
